# Blue Prune Drop and Leaf Scorch

Bill Krueger UC Farm Advisor-Emeritus, Glenn County

Richard Buchner UC Farm Advisor, Tehama County

Blue prune and, in some cases, an associated leaf scorch often develops following the rapid onset of high temperatures as occurred in June of this year (*Figure 1*). Damaged prunes color prematurely (turn blue) and usually drop from the tree. The more sun exposed fruits on the top or south side of the tree are more affected. Often the sun exposed side of the fruit will be sunken or flattened. Leaf scorch and die back may develop in leaves and twigs near the damaged fruit (*Figure 2*). When damaged leaves dry, the veins may be a darker brown than the rest of the leaf. Blue prune is associated with heat stress. Excessive heat results in damage to the fruit that is thought to produce a toxin which is transported to spurs, leaves and shoots resulting in the leaf scorch symptoms. Leaf scorch symptoms are always associated with damaged prunes. They do not occur in areas of the tree with no fruit or on young trees without a crop. Anything affecting fruit temperature can have an effect. This would include:

1. **Irrigation** – Drop and particularly scorch are generally more severe on shallow soils with limited water holding capacity or in orchards toward the end of their irrigation cycle at the onset of heat. Adequate soil moisture insures maximum evapotranspiration and cooling of the plant.
2. **Tree Position or Fruit Location** - Leaf scorch is usually worse on border trees, or on the south side of individual trees with greater sun exposure.
3. **Cultural Practices** – Blue prune appears to be less severe in orchards with cover crops than in clean tilled or drip irrigated orchards. Transpiration from an adequately irrigated cover crop should contribute to orchard cooling. In addition, a vegetated orchard floor reflects less sunlight than dead vegetation or bare ground.
4. **Nutrition** - While blue prune and leaf scorch does not appear to be directly related to potassium deficiency, anything adversely affecting tree health and condition could contribute to higher fruit temperatures. Adequate tree nitrogen levels promote vegetative growth that shades fruit from direct sunlight.

We don't have any sure ways of preventing blue prune and the associated leaf scorch. However, you can reduce the risk by making sure trees are healthy, vigorous and well supplied with water. Because the damage is caused by heat and not a disease, it should not continue to expand in the tree. Damaged wood should be pruned out during the dormant season.

## Nitrogen Budget

Another option for making nitrogen application decisions is to look at nitrogen nutrition as a nitrogen budget and aim to replace nitrogen exported from the orchard each year. Research suggests 100 to 150 pounds of nitrogen per acre for prunes depending primarily on tree age and crop load. The high rate of 150 pounds of nitrogen per acre would be more appropriate for a 4 dry ton crop load, while 100 pounds would be more typical for an “average” yielding prune orchard. Again, tissue samples can be evaluated to follow increasing or decreasing levels of tissue nitrogen.

## Visual Symptoms

Visual symptoms are a useful way to identify nitrogen deficiency and can be used in combination with other techniques to improve confidence in an orchard fertility program. Symptoms of nitrogen deficiency include reduced shoot growth and smaller slightly pale green leaves tending toward yellow as deficiency becomes more severe. Leaf tissue values are often used to confirm visual symptoms. One disadvantage is that yield losses could occur if nitrogen deficiency is not quickly diagnosed and corrected.

## Irrigation Water Analysis

The final part of nitrogen nutrition is the amount of nitrate-nitrogen in irrigation water. Prune orchard well water analysis done as part of the Integrated Prune Farming Practice (IPFP) project in 1999 showed a range of 0 to 30.2 pounds of nitrogen per acre foot of irrigation water for survey orchards in Tehama, Glenn, Butte, Sutter and Yuba counties. Nitrogen in irrigation water could be contributing significantly to an orchard's nitrogen status. Well water analysis would identify and measure this source of nitrogen. For irrigation water,  $\text{NO}_3\text{-N}$  in ppm or mg/liter times 2.72 = pounds of nitrogen per acre-foot of water. Surface water irrigation sources generally contain very little nitrogen.

## Fertilizing Mature Prune Trees

Mature, consistently producing prune trees (over 8 years old) typically require from 100 to 150 pounds of nitrogen per acre per year depending upon tree size and crop load. Careful irrigation water management is a crucial part of an efficient nitrogen management program. Soil nitrate-nitrogen can be leached down and out of the root zone with excess irrigation water, resulting in economic loss to the grower and less nitrogen available for the orchard. The primary exporter of nitrogen from the orchard is the crop, so when crop load is low it might be appropriate to reduce applied nitrogen. Likewise, a heavy crop load will require more nitrogen. Prune trees take up nitrogen most efficiently from about early April to about early September when shoot growth terminates. Split applications of nitrogen are suggested for prune production. Apply a larger percentage of the required nitrogen in the spring and a “touchup” in the summer. July leaf tissue samples are used in combination with crop load and visual symptoms to make summer nitrogen application decisions. A nitrogen budget worksheet is available in the IPFP binder published May 2003.

# 2013: A Tough Year for Cankers

Franz Niederholzer, UC Farm Advisor, Colusa/Sutter/Yuba Counties and

Joe Connell, UC Farm Advisor, Butte Co.

It has been a difficult year for the canker diseases [bacterial canker](#) and [cytospora](#) in prune orchards in the Sacramento Valley. Both of these diseases are most damaging in stressed orchards and there are no known simple cures for either infection. This article will briefly review management practices for these two damaging diseases.

**Bacterial Canker** is a disease of stressed trees and is especially damaging in stone fruit orchards. Tree damage occurs exclusively above ground, but the disease is promoted by stressful soil conditions. The stress can come from many sources including root feeding nematodes, shallow hardpan, and/or low soil nitrogen levels. The damaging bacteria (*Pseudomonas syringae*) are naturally present and normally live harmlessly on the surface of trees and weeds throughout an orchard. Tree infections occur during wet and/or cold winter and spring conditions through natural and unnatural openings in the tree such as bark pores (lenticels), opening flowers, pruning cuts, etc. Bacterial canker usually strikes young trees – 2<sup>nd</sup> to 8<sup>th</sup> leaf – in a certain region of the orchard where soil conditions result in tree stress. The disease does not survive in the tree from year to year, but the potential for another infection remains as the disease organism is always present, waiting for the “right” conditions to infect once again.

What can be done to prevent or stop bacterial canker disease? Unfortunately, there are no practices that prevent or eliminate the disease. The following practices have been shown to reduce bacterial canker damage in prune orchards in California, but not eliminate the problem:

- **Control nematodes:** Fumigate an orchard site when preplant soil samples show the presence of root feeding nematodes, especially ring nematode. Fumigation will not eliminate the risk of bacterial canker developing in the orchard. For established orchards, discuss labeled options for post-planting nematode management with your PCA.
- **Choose a less susceptible rootstock:** Where possible, plant on Lovell peach rootstock. Trees grown on this rootstock are less susceptible to bacterial canker than those grown on plum (M2624, M29C, Myro seedling, etc.) rootstocks. If the soil is too heavy for peach rootstock, use M40 plum root, the least susceptible of the plum rootstocks tested to date. Trees budded high, around 32” above the soil level, have shown the least bacterial canker infection in field studies in the Sacramento Valley. At least one grower in the region has ordered all his replants budded high.
- **Maintain soil fertility,** especially nitrogen (N). Prune trees deficient in N are more susceptible to bacterial canker infection than trees with adequate N status. High to excessive plant N status provides no additional benefit from bacterial canker compared to adequate N levels and can aggravate other diseases such as brown rot. Use of slow release, multi-nutrient fertilizers has shown benefit in UC research.

.....

**Cytospora** canker is a weak pathogen caused by the fungus *Cytospora leucostoma*. Disease spores are spread by wind and rain to bark damaged by other stresses, particularly sunburn. The fungus shows maximum growth in hot temperatures around 90°F and is particularly active in late summer to early fall. Trees planted on shallow and/or heavy textured (clay) soils are generally more likely to suffer economic damage since 1) these soils can be low in plant available K and 2) the disease spreads more rapidly in water stressed trees.

There are no chemical controls for cytospora cankers. To manage infection and reduce disease spread, avoid tree stress and remove cankered wood from the orchard and burn it. Prune to minimize sunburn potential (leave more upright branches), and, paint exposed trunks and scaffold crotches with white interior latex paint to further protect them from sunburn. Maintain adequate orchard water status, especially after harvest, and avoid potassium deficiency, spider mite or prune rust defoliation that can increase sunburn and disease potential.

Cytospora can be a major problem in older blocks. In these blocks, consider preharvest or postharvest “clean up” pruning with saws only, no loppers, using a trained crew exclusively focused on removing damaged scaffolds. This practice will reduce cytospora in the orchard and allow replacement branches to develop. If this work is done prior to harvest, removal of dead branches that can break and damage equipment during harvest will result in a smoother, less costly harvest.

To identify limbs killed or weakened by cytospora cankers, look for dark, sunken cankers on the bark of limbs showing dieback or branches where dead leaves are still attached. Cankers will have distinct zonate margins (Figure 1) that are different from the streaking and flecking in the tissue that is characteristic of bacterial cankers. Small white spots called pycnidia found on dead wood will confirm the presence of *Cytospora* (Figure 2).

Pruning out diseased limbs and burning them will reduce disease pressure and spores that can spread disease to new wood next season. Be sure to cut into healthy wood several inches to one foot below any canker symptoms. Check the cut surface of damaged limbs to ensure that all disease has been removed (Figure 3). Incomplete canker removal won't control the disease, thus wasting the time and money spent pruning. Ruthless pruning is most cost effective in the long run. Don't leave dead wood in the tree just because it has tree rope or wire attached to it. Chances are excellent that leaving this wood will hasten the spread of disease in the orchard and cost you money in the long run. Cut hard, cut hard, cut hard.

For more detailed information on disease management and for excellent photos of disease symptoms and fungus signs that will help you know what to look for, visit the IPM web page ([www.ipm.ucdavis.edu](http://www.ipm.ucdavis.edu)) and click on Agriculture and floriculture; Prune; and cytospora canker or bacterial canker (under diseases).

**Figure 1.** Cytospora cankers are detected as sunken areas on the branch where bark has been killed. Arrows point to canker edges, revealed by a knife cut in the second photo.

**Figure 2.** Pycnidia, black or white pimble-like spore producing structures, found on dead wood.

**Figure 3.** Good cut (1) below canker showing only clean bark. Bad cut (2) not far enough down the branch showing diseased bark (arrows) remaining in the tree.

# Earlier harvest in 2013?

*Franz Niederholzer, UC Farm Advisor, Colusa/Sutter/Yuba Counties*

Will the warm spring this year result in earlier prune harvest? The UC Harvest Prediction Model suggests that harvest will be several weeks earlier than the last few years. What does that mean for growers? Harvest will be when the fruit is ready, but it is a good idea to consider the following:

- **Don't let harvest sneak up on you.** Knowing the general timing of harvest in different blocks allows for more accurate and effective irrigation shut off and orchard dry-down ahead of harvest, timely equipment maintenance/preparation, and better harvest planning in general.
- **Track fruit maturity and sugar content once first color shows in fruit.** Fruit is generally mature a month after first color shows. The best indication of fruit maturity is fruit pressure. Fruit sugar levels do not accurately reflect fruit maturity. Check with local farm and orchard supply stores for "Fruit Pressure Tester". These devices cost about \$300/ea. If that cost seems too high, why not split the cost with a neighbor? Fruit pressure should be checked about once a week, leaving plenty of time for sharing a pressure tester between two or more operations. Every prune grower should have ready access to this tool. Fruit is mature between 3-4 lbs internal pressure.

There is no more important time in an orchard business than harvest. Proper harvest timing results in the best return to the grower from delivering the highest quality fruit possible under the conditions of that season. Harvesting too early leaves money in the orchard due to higher dry-away and lower yield. Harvesting too late means running the risk of fruit drop on the orchard floor if wind, rain, and/or cool weather occur suddenly. Not all the crop can be harvested at optimum maturity, but careful planning will give you the best overall results.

## SAVE the DATE

### 2014 Tehama Prune Day

### February 21, 2014

Red Bluff Elks Lodge

*NOW* — Available to purchase at the Tehama Cooperative Extension Office

## PRUNE PRODUCTION MANUAL

from UC Agriculture and Natural Resources

Chapters include:

- An industry overview
- A detailed description of prune biology
- Information on understanding soils, varieties, irrigation and fertilization
- Pest management techniques
- A lesson on harvest and postharvest management

The breadth of expertise and knowledge contained in the 320 pages of this manual, along with the more than 300 photos and 56 color illustrations make this one of the most comprehensive prune production manuals in the world. Inside you'll find the professionalism, expertise and science-based answers you've come to expect from the University of California. Copies are now available to purchase at the Tehama Cooperative Extension Office:

**\$45.00** • **ANR Pub 3507**

<http://www.ipm.ucdavis.edu/PMG/selectnewpest.prune.html>  
**Check out this website for year round Pest Management information.**

- Fungicide Efficacy for Prune Diseases
- Monitoring for Aphids
- Pheromone Traps
- Fruit Evaluation at Harvest
- Dormant Spur Sampling
- Toxicities of Insecticides & Miticides used in Prunes to Natural Enemies and Honey Bees
- Relative Impact on the timing of pesticide applications on natural enemies and water quality

**Find more information on:**

- Diseases affecting Prunes
- Identify and learn how to treat Insect and Mite problems

# FRUIT & NUT NOTES

# SACRAMENTO VALLEY REGIONAL PRUNE NEWSLETTER

*The “SACRAMENTO VALLEY REGIONAL PRUNE NEWSLETTER” is a collaborative effort of prune research specialists working together to provide Sacramento Valley growers and industry leaders the latest research and information effecting walnut production in today’s changing environment. This newsletter will be published quarterly, be sure to look for upcoming issues!*

The University of California ) Division of Agriculture & Natural Resources (ANR) prohibits discrimination against or harassment of any person in any of its programs or activities on the basis of race, color, national origin, religion, sex, gender identity, pregnancy (which includes pregnancy, childbirth, and medical conditions related to pregnancy or childbirth), physical or mental disability, medical condition (cancer-related or genetic characteristics), genetic information (including family medical history), ancestry, marital status, age, sexual orientation, citizenship, or service in the uniformed services (as defined by the Uniformed Services Employment and Reemployment Rights Act of 1994: *service in the uniformed services* includes membership, application for membership, performance of service, application for service, or obligation for service in the uniformed services).

University policy also prohibits retaliation against any employee or person in any of its programs or activities for bringing a complaint of discrimination or harassment pursuant to this policy. This policy also prohibits retaliation against a person who assists someone with a complaint of discrimination or harassment, or participates in any manner in an investigation or resolution of a complaint of discrimination or harassment. Retaliation includes threats, intimidation, reprisals, and/or adverse actions related to employment or to any of its programs or activities.
